

Project Idea:

As a group we will develop a client-server based ticket application. For this project we will specify it for a system of helpdesk type tickets. This implies that a user can submit their information/email and store a process of what the user is having problems with this can allow a generated response to send to the user that a person with access to log in can do so and access a database of these tickets to respond to at their discretion. The server will manage the ticket database and remain up so that at any point the client will be able to reach out and put in "requests". While the client will remain a user interface where you can choose to submit a ticket or log in to see them. This project will demonstrate Client server communication.

Requirements:

- Client
 - Connect to the ticket server.
 - View list of tickets if correct login.
 - Create tickets.
 - Disconnect after ticket submission.
 - Handle invalid input.
- Server
 - Contain ticket database.
 - Print out clean format to admin user.
 - Maintain timestamp for ticket.
 - Validate admin user.
 - Send structured response.

Protocol Design:

For our design of this project we will use the format: FOR_EXAMPLE | "Message here". This will be used in conjunction with \n to clearly label responses and messages to and from for any part of the project.

Work Division:

- Member A will work on client UI interface and Login portion of the project.
- Member B will work on the client side communication between the server and itself.
- Member C will work on the server side communication between the client UI and the database.
